

TRIAL-OPS WORKED EXAMPLE • STUDY CP-101

A day on the hybrid trial-ops platform

Five automations fire across one day — recurrent QC, SOP knowledge, eTMF filing, timeline cascade, and risk-based monitoring. Each one follows the same shape: a trigger, an AI-drafted proposal, and a human who approves. Nothing reaches a validated system of record without that approval.

Illustrative. Sensitive data stays on the LOCAL model; validated systems (EDC / eTMF / CTMS) own every record; a human approves every action.

Every automation: trigger → AI drafts → a human approves

The rule (every one of the 75 automations): the agent **drafts a proposal** into a **human-approval queue**; nothing is filed, sent, or changed in a validated system until a human approves. Sensitive data → LOCAL; non-sensitive → cloud.

08:00

Nightly QC triage

a data discrepancy → a drafted query

10:30

SOP knowledge (RAG)

a CRA's procedure question → a cited answer

13:00

eTMF filing

a visit report arrives → a filing proposal

15:00

Timeline cascade

a milestone slips → a Smartsheet update

16:30

RBQM / KRI

a KRI breaches → a flag to the PM

Five automations, one day, one shape — the agent does the drafting; a human owns every approval and every validated record.

A nightly check catches a data discrepancy

Participant-level → LOCAL, zero egress. The agent drafts the query; the data manager approves and issues it in the validated EDC.

A CRA asks a procedure question

Non-sensitive SOP retrieval → cloud, with citations. The answer points to the controlled SOP; a human verifies before acting.

A monitoring visit report arrives

The agent proposes the eTMF zone, location, and metadata; the TMF specialist approves and files in the validated eTMF.

A milestone slips — the schedule must follow

Non-sensitive timeline logic → cloud draft. The agent computes the cascade; the PM reviews and applies the change.

A risk indicator breaches its tolerance

The agent packages the KRI breach with its evidence; the PM / central monitor decides the response. The AI flags, never acts.

The platform drafts; the humans approve; the validated systems own the records.

One shape, every automation

Trigger → AI draft → human approval. The drafting is automated; the approval and the record are not.

Sensitivity routed the engine

Participant-level QC and the RBM signal stayed LOCAL (zero egress); de-identified SOP / filing / timeline work went to CLOUD.

Validated systems stayed authoritative

The EDC issued the query, the eTMF filed the document, Smartsheet held the timeline — the agent wrote to none of them directly.

The payoff

The busywork — drafting queries, classifying docs, computing cascades, packaging signals — is automated; judgment and accountability stay human.
